Target Auto Buyer v3.1

An experimental browser userscript for monitoring Target product availability and assisting with cart and checkout steps. It is not an official Target product and cannot guarantee stock, successful checkout, or an order.

Version 3.1

Version 3.1 adds a movable, resizable, minimizable dashboard; stock-check log messages; and safer Place Order handling. Target may change its page or API at any time, so selectors and behavior can stop working without notice.

Key Features

■■ 1. Ultra-Low Latency & High-Speed Polling

- ** Drop Mode:** Uses a 250ms API polling interval while enabled.
- **Normal Polling Mode:** Uses a randomized interval between the configured minimum and maximum.
- **Drop Timer:** Displays a countdown and uses 250ms polling during the configured 30 seconds before the drop time.
- **Polling limits:** Rapid repeated requests may be rate-limited or blocked. Use monitoring only when needed.

2. Intelligent Add-to-Cart Flow

- **Direct Cart Drawer Detection:** Targets the live Target slide-out drawer (`Added to cart`, `View cart & check out`, `custom-quantity-picker`).
- **Auto-Decline Protection Plans:** Automatically dismisses warranty/protection plan modals without stalling the flow.
- **Cart Page Auto-Advance:** Looks for a supported checkout button on the cart page.
- **ATC Retries:** Retries when cart confirmation is not detected; after the retry limit it may continue to checkout without confirmed cart status. Verify the cart contents yourself.

3. Rapid Single-Pass Checkout

- **200ms Fast Execution Loop:** Continuously evaluates checkout state.
- **CVV Auto-Fill:** Fills the CVV field when configured. Login, mandatory verification, CAPTCHA, and other prompts may require manual action.
- **Single Place Order Submission:** Clicks Place Order once per loaded checkout page, then waits for an explicit confirmation signal. A page reload starts a new script page session, so the bot cannot guarantee duplicate prevention across reloads.
- **Best-Effort Order Status:** Looks for specific confirmation elements/headings while the checkout handler is running. If checkout ends without detecting one, it asks you to verify the order manually. Confirmation detection may fail if Target changes its page or navigation.

- **Cart Error Detection:** Detects some item-removed and sold-out messages. It does not guarantee recovery or a successful retry.

4. Diagnostics & Live HUD

- **Real-Time Floating Control Panel:** Drag the header to move the dashboard; use Large/Compact and minimize/restore controls. Its position and size preferences are saved.
- **Live Stock Log:** Displays each API stock-check attempt and its result; keeps the most recent 300 log lines.
- **Live Performance Metrics:** Tracks timestamps and calculates latency for each stage:
- `Stock → ATC`
- `ATC → Cart Confirmed`
- `Cart → Checkout Started`
- `Total Time to Order Confirmation` when confirmation is detected
- **Session Check:** Checks the `/co-cart` endpoint before starting. This does not guarantee that your session is authenticated or that checkout will succeed.

■ Installation

Step 1: Install a Userscript Manager

Install one of the following browser extensions on Chrome, Edge, Brave, or Firefox: - Tampermonkey *(Recommended)* - Violentmonkey

Step 2: Install Target Auto Buyer

1. Open your userscript manager dashboard (click the extension icon in your browser toolbar).
2. Click **Create a new script** (+ tab).
3. Delete any default template code.
4. Open `Target Auto Buyer.js` and copy the entire contents.
5. Paste into the editor and press **Ctrl + S** (or **Cmd + S** on macOS) to save.
6. Verify the script is enabled in the Tampermonkey dashboard.

How to Use

1. Pre-Drop Preparation (Crucial!)

Before running the bot: 1. **Log in to your Target account** prior to the drop. 2. Ensure you have a **default shipping address** and **default payment card** saved in your Target wallet. 3. Make sure you know your card's **CVV**.

2. Configure the Bot HUD

Navigate to any Target product page (e.g. `https://www.target.com/p/...`). A floating red dashboard will appear in the bottom-right corner:

Setting	Description	Recommended Setting
CVV	3 or 4 digit security code for your saved card.	Your card's CVV
Max Price ($)	Attempts to hold when the product page price is above the entered amount. **This is not a reliable purchase limit; do not rely on it as a safety control.**	Set a value, but verify price yourself
Quantity	Number of items to select (1–10).	1
Drop Mode ()	Toggles 250ms API polling.	Enable only when needed
Drop Time	Date & time when the item goes live.	Set to scheduled release time

Settings are saved as they are changed via the userscript manager. The dashboard currently provides a CVV field; it does not provide a password field.

Use the **Large / Compact** button in the dashboard header to resize the panel, or the – button to minimize it; these preferences are remembered. Drag the header to move the dashboard, and its position is saved. While monitoring, each stock-check attempt and its result appears in the dashboard log.

3. Launching the Bot

1. Navigate to the product page you want to monitor.
2. Click **Start Bot**. The status will turn green (`Running`).
3. If the item is out of stock, the bot will begin dual-mode monitoring (RedSky API + button observer). The observer will not click while the product page still reports “Out of Stock,” even if an ATC-like control is present.
4. Once the out-of-stock status clears and an enabled ATC control is available, the bot may attempt to add the item to cart and proceed through supported checkout prompts.
5. The bot submits Place Order at most once while the current checkout page remains loaded. It may show **Awaiting Confirmation**. If a recognized confirmation appears while its checkout handler is active, it reports **Order Confirmed**; if checkout ends without one, verify your Target account and email before taking any further action. Never click Place Order again just because the bot status is uncertain. A page reload starts a new script page session, so duplicate prevention is not guaranteed across reloads.

Important: The Max Price setting is not a guaranteed purchase cap. The stock-monitoring flow may still attempt to add an item when the page price is above the configured amount. Do not leave the bot unattended or rely on the price setting to prevent an unwanted purchase. Verify the item, price, quantity, shipping, and payment details before any order submission.

How It Works Under the Hood

```
flowchart TD A[Product Page Loaded] --> B{Item in Stock?} B -- No --> C[Dual-Mode
Monitoring] C -->|API polling at configured interval| D{Stock Detected?} C -->|DOM
Mutation Observer| D D -- No --> C D -- Yes --> E{Out-of-stock status cleared?} E -- No
--> C E -- Yes --> F{ATC Button Ready on DOM?} F -- Yes --> G[Click ATC Immediately] F --
No --> H[Reload Page] --> G B -- Yes --> G G --> I[MutationObserver Listens for Cart
Drawer] I -->|Cart Confirmed / Timeout| J[Instant Redirect to /checkout] J --> K{Checkout
Screen} K -->|Sign-in or verification prompt| L[Complete prompt manually if required] K
-->|CVV Prompt| M[Auto-fill CVV & Confirm in 1 Pass] K -->|Review Order| N[Click Place
Order] N --> O{Confirmation detected?} O -- Yes --> P[ Order Confirmed] O -- No --> Q[Stop
and Verify Order Manually]
```

Safe Testing Guide

Test the interface without placing an order:

1. Open a product page and check that the dashboard appears.
2. Test the Large/Compact, minimize/restore, and drag controls.
3. Set a future Drop Time and confirm the countdown updates.
4. If testing cart or checkout navigation, stop the bot before Place Order. Do not use an incorrect CVV as a dry run; a real order may still be accepted or the result may be ambiguous.
5. Treat Max Price as informational only, not as protection against an unintended purchase.

■ Advanced Configuration (Code Level)

All timing thresholds and constants are cleanly declared at the top of `Target Auto Buyer.js`:

```
const CFG = { POLL_MIN_MS: 500, // Normal min polling interval POLL_MAX_MS: 1500, //
Normal max polling interval DROP_MODE_POLL_MS: 250, // Ultra-aggressive drop interval
ADAPTIVE_LEAD_SEC: 30, // Seconds before drop time to trigger drop mode API_MAX_RETRIES:
3, // API retries on server/network errors API_RETRY_BASE_MS: 150, // Backoff base for
retries ATC_MAX_RETRIES: 3, // Max ATC click attempts CART_CONFIRM_TIMEOUT_MS: 4000, //
Wait before optimistic checkout jump CHECKOUT_INTERVAL_MS: 200, // Checkout cycle tick
rate STARTUP_POLL_MS: 100, // Fast startup poll interval STARTUP_MAX_WAIT_MS: 5000, // Max
wait for initial page elements };
```

Frequently Asked Questions

Could monitoring be rate-limited? Yes. Frequent requests may be limited or blocked, and Target may present additional verification. Use the bot only when needed and follow Target's applicable terms. **What happens if a CAPTCHA or verification prompt appears?** The bot does not solve CAPTCHAs or mandatory verification challenges. Complete any supported prompt manually and check the page before continuing. **Does an order-confirmed status guarantee a successful purchase?** No. Detection depends on the current Target page structure and can fail or misidentify a page. Verify orders in your Target account and confirmation email. **Can I run multiple tabs?** Yes! The script uses isolated tab-level running states (`sessionStorage`), meaning each browser tab can monitor a different product independently without cross-tab conflicts.
